#4

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Inventors: Taylor, et al.
Serial No: 09/898,900
Filed: July 3, 2001
For: ASPHALT ADDITIVE MIXING APPARATUS AND METHODS

Examiner: Not yet assigned
Art Unit: 3673

Claim For Priority Under 35 U.S.C. § 119 In Utility Application

Box Patent Application
Assistant Commissioner of Patents
Washington, D.C. 20231

Sir:

Priority under 35 U.S.C. § 119 is hereby claimed to the following priority document, filed in a foreign country within twelve (12) months prior to the filing of the above-referenced United States utility patent application:

Country/Region	Priority Document Appl. No.	Filing Date
GB	0016442.6	04 July 2000

A certified copy of the above listed priority document is submitted herewith. Prompt acknowledgement of this claim and submission is respectfully requested.

Respectfully submitted,

Robert E. Hunt, Reg. No. 39,231
WOLF, GREENFIELD & SACKS, P.C.
600 Atlantic Avenue
Boston, MA 02210-2211
Tel: (617) 720-3500

Docket No.: H0075/7076

INVESTOR IN PEOPLE

The Patent Office
Concept House
Cardiff Road
Newport
South Wales
NP10 8QQ

the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation and Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents originally filed in connection with the patent application identified therein together with the statement of inventorship and of right to grant of a Patent (Form 7/77), which was subsequently filed.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in the certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., p.l.c. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Patents ADP number (if you know it):

ASPHALT ADDITIVE MIXING APPARATUS AND METHOD

The present invention relates to the production of high quality pavement. In particular, the present invention
5 relates to an apparatus and method for incorporating pelletised additives into thin surface dressings.

Stone Mastic Asphalt (SMA), an example of a thin surface dressing, was developed in the early 1970s in Germany
10 (originally to resist the wear of studded tyres) where to date, over 250 million square metres of highway have been paved with this product. The successful production of SMA is only possible with the use of stabilising additives in the form of highly specialised cellulose
15 fibres. These prevent excessive drainage of the asphalt binding agent (bitumen).

Due to its excellent characteristics and performance, SMA has been adopted in many countries, including the
20 Netherlands, France, Switzerland, UK, Norway, Finland, Sweden, Denmark, Turkey, Greece, Poland, Japan, Israel and the USA.

The advantages of thin surface dressings over
25 conventional road surface applications are now well recognised and its use is increasing at a steady pace in the UK.

Asphalt production plants which manufacture blends of
30 aggregate and bitumen for use in the production of thin surface dressings, were not designed with these new

products in mind. Such plants consist of large storage vessels holding bulk raw materials, such as aggregate and bitumen, which are then conveyed to a central elevated mixing box for blending. The asphalt mixing box typically has a height similar to that of a three or four storey building. The raw materials are typically mixed in a ratio of 1 tonne of aggregate to 200 kg of fillers and binders, the latter typically comprising 70-100 kg of bitumen. Blending takes place at an elevated temperature of typically 170°C. However, the industry is moving towards production of technically more sophisticated thin surface dressings that require the incorporation of multiple additives. In contrast to the relatively large proportion of bitumen in a finished asphalt product, these further additives are incorporated in relatively small amounts, such as 3 kg of fibre, 10 kg of pigment and 5 kg of a polymer modifier per tonne of aggregate.

Accordingly, these new products are manufactured today either by manual addition of the multiple additives into the asphalt mixing box or by means of a supply system as shown in Fig. 1. Both techniques have disadvantages as follows.

Manual addition of additives into the mixing box creates health and safety hazards for operators, as the additives can be dusty and of a dangerous nature. Manual addition also has a tendency to result in inconsistency in the blending process, accidental losses and inconsistent end products.

On the other hand, the additive supply system shown in Fig. 1, which reduces these hazards, is only designed to

incorporate a single additive volumetrically into the asphalt mixing box.

The additive supply system shown in Fig. 1 comprises components and operates as follows. A bulk silo 10 for storing an additive in pelletised form is filled by means of a filler pipe 12. Additive can be added to the bulk silo 10 by being blown up filler pipe 12. A safety ladder 14 enclosed by safety rails 16 provides access to a hinged roof hatch 18 at the top of bulk silo 10. A high level probe 20 located at the top of bulk silo 10 indicates when the silo is full. Gas is exhausted down exhaust pipe 22, to which a cyclone dust collector 24 is fitted. The bulk silo 10 is emptied by agitation of its contents at low level using rotary electric vibrators 26. A level probe 28 and an emergency low level probe 30 respectively indicate when the bulk silo 10 is nearly or completely empty. Additive leaving the silo is conveyed by a supply auger 32 to the asphalt mixing box. The supply auger may be provided with a calibration or sampling point 34 and an acoustic flow detection sensor 36. The auger 32 is driven by a drive unit 38 which draws additive to outlet 40 and into the asphalt mixing box. The elevated asphalt mixing box is accordingly fed with additive from the bulk silo 10 from above. The quantity of additive added to each batch of asphalt is controlled simply by the run duration time of drive unit 38.

On the other hand, asphalt production plants are often sited in restricted areas where storage space is limited. The current design of these plants requires that storage vessels for additives, such as that shown in Fig. 1, are located significant distances from the asphalt mixing

box. This is because supply auger 32 shown in Fig. 1 cannot be oriented at an angle greater than about 45° to the horizontal, otherwise additive pellets drop back down the auger under gravity and the flow of additive from silo 10 to the asphalt mixing box is impeded. Accordingly, storage facilities for each new additive required would similarly need to be sited at an appreciable distance from the asphalt mixing box and augered in. If the asphalt product in question requires a number of additives, storage systems as shown in Fig. 1 would need to be replicated several times over, causing potential problems siting the additive supply units around the asphalt mixing box due to lack of space. With such a plurality of additive supply systems, it also remains difficult to achieve a good blend of additives, giving a similar disadvantage to the manual addition of such additives.

Furthermore, the industry is also looking to create new asphalt products with a wide range of colours in response to the drive towards improved road safety and to aesthetic considerations in speciality applications, such as driveways or parking zones where standard black asphalt is less preferred. Currently these needs are not being met, with only a narrow range of colours being available. Existing asphalt manufacturing plants have in general little flexibility for rapid changes in the additive formulations used without significant loss of out-of-specification end products.

30

An object of the present invention, therefore, is to overcome the disadvantages exhibited by these conventional techniques and to permit the manufacture of

thin surface dressings incorporating one or more pre-blended additives in a precise, reproducible manner.

Accordingly, in a first aspect, the present invention provides an apparatus for preparing a blend of additives for incorporation in an asphalt, said apparatus comprising: a receptacle for sequentially receiving one or more of said additives; weighing means connected to said receptacle for measuring respective gravimetric amounts of said additives; mixing means for mixing said additives in said receptacle into a blend; and transfer means for directing said blend of additives from said receptacle to means for delivering said blend to an asphalt mixing box.

In a second aspect, the present invention also provides a method of blending additives for incorporation in an asphalt, said method comprising: sequentially feeding one or more of said additives into a receptacle; weighing each additive to achieve a desired proportion thereof in a desired total amount of said additives; mixing said additives in said receptacle into a blend; and transferring said blend from said receptacle to means for conveying said blend to an asphalt mixing box.

In a third aspect, the present invention further provides an apparatus for delivering additives for incorporation in an asphalt to an asphalt mixing box, said apparatus comprising: means for preparing a blend of said additives having an input for said additives locatable at a level substantially lower than an input for said additives to said asphalt mixing box; a transfer pipe connecting an output of said blending means to the input of said asphalt mixing box; and a pneumatic pressure source

connected to said transfer pipe for conveying said blend along said transfer pipe from the output of said blending means to the input of said asphalt mixing box.

5 In a fourth aspect, the present invention further provides a method of delivering additives for incorporation in an asphalt to an asphalt mixing box, said method comprising: supplying said additives to means for preparing a blend of said additives at a level
10 substantially lower than an input for said additives to said asphalt mixing box; and pneumatically conveying said blend of additives from an output of said blending means to the input of said asphalt mixing box.

15 Preferably an apparatus according to the third aspect of the invention uses an apparatus according to the first aspect of the invention as means for preparing a blend of said additives. In other words, an apparatus according to the first aspect of the invention preferably uses an
20 apparatus according to the third aspect of the invention as means for delivering said blend to an asphalt mixing box. Likewise, a method according to the fourth aspect of the invention preferably further comprises, after said supplying step and before said conveying step, blending
25 said additives by a method according to the second aspect of the invention. In other words, a method according to the second aspect of the invention preferably further comprises a method of delivering said additives to an asphalt mixing box according to the fourth aspect of the
30 invention.

In a preferred embodiment, the apparatus according to the first aspect of the invention further comprises a control system having an input from said weighing means and

control outputs to an inlet of said receptacle and to said mixing means and said transfer means, said control system being programmable to regulate receipt of said additives through said receptacle inlet on the basis of
5 gravimetric amounts of additives measured by said weighing means until a desired total amount of said additives in desired proportions thereof is achieved, and to operate said mixing means and said transfer means sequentially thereafter.

10

The features of an apparatus according to the first aspect of the invention and of a method according to the second aspect of the invention give improved performance, consistency and range of end products after incorporation
15 of the additives into an asphalt. Accordingly, these aspects of the invention provide an effective manner of creating a wide palette of easily reproducible coloured thin surface dressings, such as those required for speciality applications, by blending pelletised colour
20 pigments to create a consistent range of graded colours. The improved accuracy of desired proportions of additives and thorough pre-blending achieved by these aspects of the invention prior to their incorporation into an asphalt give improved performance characteristics due to
25 the improved uniformity of dispersion of the additives in question through the asphalt when laid as a pavement.

The third and fourth aspects of the invention provide advantages in the siting and distribution of additive
30 storage vessels around an asphalt mixing box. Since the means for preparing a blend of said additives has an input for said additives locatable at a level substantially lower than an input for said additives to said asphalt mixing box, additive storage vessels may be

located very close to said blending means. This is because augers delivering additives from said additive storage vessels need only cover a small horizontal distance in order to lift additives from the respective storage vessels to a height sufficient to be input to the blending means in comparison to the much larger horizontal distance that would otherwise be required to lift additives from the respective storage vessels to the top of an asphalt mixing box. On the other hand, since a pneumatic pressure source is used to convey a blend of additives from an output of said blending means to an input of said asphalt mixing box, the transfer pipe connecting the output of the blending means to the input of the asphalt mixing box may include a vertical portion, which would not be achievable with an auger. For this reason, the blending means may be located very close to the asphalt mixing box. A large number of additive storage vessels may therefore be sited in close proximity to an asphalt mixing box, which has previously been impossible. The pneumatic pressure source may either be a blower or a vacuum pump.

Preferably, the additives are blended and delivered to the asphalt mixing box in pelletised form. This aids both the blending and the delivery procedures.

Further features and advantages of the present invention will be better understood by reference to the following description giving in association with the accompanying drawings, in which:

Fig. 1 is a side elevational view of a conventional supply system for providing an additive to an asphalt mixing box;

Fig. 2 is a side elevational view of an additive mixing apparatus according to an embodiment of the invention, shown in situ with a plurality of additive storage
5 vessels;

Fig. 3 is a plan view of the arrangement shown in Fig. 2;

Fig. 4 is a side elevational view of the same embodiment
10 of the invention shown in situ with a single additive storage vessel;

Fig. 5 is a plan view of the arrangement shown in Fig. 4;

15 Fig. 6 is a close-up side elevational view of this embodiment of the invention, showing the internal components thereof;

Fig. 7A is a side elevational view of the exterior of
20 this embodiment of the invention;

Fig. 7B is a plan view of the exterior of the embodiment of the invention shown in Fig. 7A;

25 Fig. 7C is a front elevational view of the exterior of the embodiment of the invention shown in Fig. 7A; and

Fig. 7D is a rear elevational view of the exterior of the embodiment of the invention shown in Fig. 7A.

30

Referring firstly to Fig. 2, an embodiment of an apparatus according to the invention, represented generally by reference numeral 200, is shown in association with a plurality of additive storage vessels.

The additive storage vessels may comprise one or more bulk silos 10 of the type also shown in Fig. 1 and/or one or more cari silos 100. Whereas bulk silos 10 are permanently sited, a cari silo may be removed and replaced using a fork-lift truck. Apparatus 200 is connected to each of the additive storage vessels associated therewith by an independent centreless auger for each respective storage vessel as indicated by reference numerals 32 in Fig.3. Each additive is stored in pelletised form in a respective silo of appropriate size defined by the expected addition rate of the additive in question to the thin surface dressings to be prepared. As shown in Fig. 2, apparatus 200 is provided with a transfer pipe 210, by means of which blended pelletised additives are transferred by a positive pressure pneumatic conveying system to an elevated asphalt mixing box (not shown), where they are combined with the bulk components such as aggregate and bitumen.

Figure 4 shows apparatus 200 in association with a single cari silo 100. Apparatus 200 comprises a material reception hopper 202 which enables precise, reproducible batch quantities of pelletised additives to be weighed in controlled conditions using one or more high-accuracy load cells 214 (shown later in Fig. 6). Apparatus 200 further comprises a blower 204, a pneumatic slide valve 206, a rotary valve 208, transfer pipe 210 and a silencer 212, all of which are described in greater detail below in association with Fig. 6. Cari silo 100 is provided with a hinged top hatch 118 and visual level indicators 128, and is mounted on the weatherproof slide 104 of a base unit 106. Base unit 106 further comprises a fixed ladder 114 with safety rails 116, fork lift channels 102 to permit removal of cari silo 100 from base unit 106,

and an auger pick-up unit 108 for connection of cari silo 100 to supply auger 32. Auger pick-up unit 108 is designed to minimise losses of additive by use of a valve at the base of the cari silo, which seals the silo when
5 disconnected from auger 32.

Fig. 5 shows the same arrangement as above, in which the cari silo and apparatus according to this embodiment of the invention are again represented by reference numerals
10 100 and 200, respectively.

A close-up side elevational view of the apparatus 200 is shown in Fig. 6, which reveals the internal components of apparatus 200. Apparatus 200 comprises components and
15 operates as follows. Material reception hopper 202, which typically has a capacity of 200 litres, receives pelletised additives from one or more supply augers 32. One or more load cells 214, which are tared to account for the weight of material reception hopper 202 when
20 empty, permit gravimetric addition of pelletised additives to hopper 202 in desired proportions. In the present embodiment, load cell 214 has a capacity of 250 kg and is provided with anti-vibration, anti-shock loading mounting pads. In an alternative embodiment not
25 shown in Fig. 6, material reception hopper 202 may instead be suspended from three load cells each having a capacity of 100 kg, which themselves are suspended from the main body of apparatus 200. Sequential addition of additives of known weight from their respective storage
30 vessels gives an extremely flexible system. With these embodiments, a weighing accuracy of $\pm 0.5\%$ can be achieved. This control eliminates problems with over-dosage and accidental spillage of the pelletised additives, which are expensive. Following addition of

pelletised additives in desired proportions to the weigh
hopper 202 as determined by means of load cell 214, the
contents of hopper 202 are mixed by means of a vertical
auger centrally located therein, paddles, or similar
5 mixing means (not shown in Fig. 6).

Once mixed, the pelletised additives are transferred from
material reception hopper 202 via a rotary valve 208
located at the bottom of the hopper. From weigh hopper
10 202, the mixture of pelletised additives is directed by
rotary valve 208 to transfer pipe 210. Rotary valve 208
is driven by a motor having a power of typically 0.75kW
to provide a rotor speed of from 50 to 70 rpm. The
pelletised additives are then forced along transfer pipe
15 210 by air from blower 204. The rotary valve 208
controls the flow of material along transfer pipe 210 to
give a constant rate of flow therein. The rate of
rotation of rotary valve 208 is linked to the operation
of blower 204. This is sequenced by means of a control
20 timer provided on a main control panel of apparatus 200
(not shown in Fig. 6). In two preferred embodiments,
blower 204 may have a power of 5.5kW and operate at 2900
rpm or 7.5kW and operate at 3000 rpm, providing a
conveying rate of the pelletised additives along transfer
25 pipe 210 of between 12 and 24 m³ per hour, according to
throughput requirements. Approximate throughput rates,
expressed in tonnes per hour, are shown in Table I.

TABLE I

Horizontal length of transfer pipe 210	Vertical length of transfer pipe 210	No. of 90° bends in transfer pipe 210	Approx. throughput	
			5.5kW blower	7.5kW blower
5m	7m	2	11 t/h	14 t/h
5m	10m	3	9 t/h	11 t/h
10m	10m	2	9 t/h	12 t/h
10m	15m	3	7 t/h	9 t/h
15m	15m	4	6 t/h	8 t/h
15m	20m	5	5 t/h	6 t/h

5 In order to adjust the rate of flow of air output by blower 204 to transfer pipe 210, apparatus 200 is provided with a slide valve 206. Slide valve 206 is pneumatically operated to vary the air output from blower 204 to transfer pipe 210 according to requirements. Air
10 output by blower 204 can be diverted from transfer pipe 210 by slide valve 206 to an exhaust outlet. This permits the blower to be kept running at a constant rate when the rate of flow of air from blower 204 to transfer pipe 210 needs to be varied according to requirements or
15 even when no additives are to be propelled along transfer pipe 210 at all. Adjusting the rate of revolution of blower 204 or switching blower 204 on and off, both of which shorten its working lifetime, are thereby avoided. This has the advantage of extending the working lifetime
20 of the blower. A silencer 212 is fitted to the exhaust from slide valve 206 for health and safety reasons.

Figs. 7A to 7D show the exterior appearance of apparatus 200. The components shown in Fig. 6 and described above

are contained within an enclosure, which is preferably manufactured from Plastisol™ coated steel. The enclosure is provided with removable access panels to permit servicing of the internal components of apparatus 200. Typical exterior dimensions of the enclosure are 2.4m in length by 1.3m in width by 1.9m in height.

Apparatus 200 is very versatile because storage vessels for the pelletised additives, particularly if cavi silos 100 of the type shown in Fig. 4, are interchangeable, allowing different pelletised additives to be combined and mixed in desired proportions. Pelletised fibres, colour pigment pellets, binders and polymers may therefore all be added to an asphalt mixing box by means of the apparatus 200 in desired proportions and at the same time in a well pre-blended condition. As apparatus 200 is fully automated, the health and safety risks of manual handling of non-pelletised additives are eliminated. The invention also keeps asphalt mixing cycle times to a minimum by eliminating the need for dry mixing of non-pelletised additives prior to the wet mix process conducted in the main asphalt mixing box through pre-blending of pelletised additives by means of apparatus 200. This enables better additive dispersion in the asphalt product and consistent product density, through the use of pelletised additives.

Claims:

1. An apparatus for preparing a blend of additives for incorporation in an asphalt, said apparatus comprising:
 - 5 a receptacle (202) for sequentially receiving one or more of said additives;
 - weighing means (214) connected to said receptacle for measuring respective gravimetric amounts of said additives;
 - 10 mixing means for mixing said additives in said receptacle into a blend; and
 - transfer means (208) for directing said blend of additives from said receptacle to means for delivering said blend to an asphalt mixing box.
- 15 2. An apparatus according to claim 1, comprising one or more inlets each respectively compatible with an outlet from a centreless auger (32).
- 20 3. An apparatus according to claim 1 or claim 2, wherein said weighing means comprises one or more load cells tared to account for the weight of said receptacle when empty.
- 25 4. An apparatus according to any one of claims 1 to 3, wherein the mixing means comprises a vertical auger centrally located in said receptacle.
- 30 5. An apparatus according to any one of claims 1 to 4, wherein the transfer means comprises a motor-driven rotary valve.
6. An apparatus according to any one of claims 1 to 5, further comprising a control system having an input from

said weighing means and control outputs to an inlet of said receptacle and to said mixing means and said transfer means, said control system being programmable to regulate receipt of said additives through said
5 receptacle inlet on the basis of gravimetric amounts of additives measured by said weighing means until a desired total amount of said additives in desired proportions thereof is achieved, and to operate said mixing means and said transfer means sequentially thereafter.

10

7. An apparatus according to any one of claims 1 to 6, adapted to blend pelletised additives.

8. A method of blending additives for incorporation in
15 an asphalt, said method comprising:

sequentially feeding one or more of said additives into a receptacle;

weighing each additive to achieve a desired proportion thereof in a desired total amount of said
20 additives;

mixing said additives in said receptacle into a blend; and

transferring said blend from said receptacle to means for conveying said blend to an asphalt mixing box.

25

9. A method according to claim 8, further comprising controlling said sequential feeding of said additives on the basis of an output of said weighing operation.

30 10. A method according to claim 8 or claim 9, wherein said sequential feeding step comprises feeding said additives into said receptacle in pelletised form.

11. An apparatus for delivering additives for incorporation in an asphalt to an asphalt mixing box, said apparatus comprising:

5 means for preparing a blend of said additives having an input for said additives locatable at a level substantially lower than an input for said additives to said asphalt mixing box;

10 a transfer pipe (210) connecting an output of said blending means to the input of said asphalt mixing box; and

a pneumatic pressure source (204) connected to said transfer pipe for conveying said blend along said transfer pipe from the output of said blending means to the input of said asphalt mixing box.

15

12. An apparatus according to claim 11, wherein said transfer pipe includes a vertical portion thereof.

13. An apparatus according to claim 11 or claim 12,
20 further comprising a valve (206) for regulating pressure developed by said pneumatic pressure source.

14. An apparatus according to any one of claims 11 to 13, further comprising means (212) for diverting pressure
25 developed by said pneumatic pressure source from said transfer pipe to an exhaust.

15. An apparatus according to any one of claims 11 to 14, adapted to deliver pelletised additives to said
30 asphalt mixing box.

16. An apparatus according to any one of claims 11 to 15, wherein said means for preparing a blend of said

additives comprises an apparatus according to any one of claims 1 to 7.

17. An apparatus according to claim 16 as dependent upon
5 claims 6 and 14, wherein said control system has a control output to said means (212) for diverting pressure from said transfer pipe (210) to said exhaust and is programmable to operate said diverting means in step with said transfer means (208).

10

18. A method of delivering additives for incorporation in an asphalt to an asphalt mixing box, said method comprising:

supplying said additives to means for preparing a
15 blend of said additives at a level substantially lower than an input for said additives to said asphalt mixing box; and

pneumatically conveying said blend of additives from an output of said blending means to the input of said
20 asphalt mixing box.

19. A method according to claim 18, wherein said pneumatic conveying step includes pneumatically conveying said blend of additives vertically.

25

20. A method according to claim 18 or claim 19, further comprising regulating the rate of said pneumatic conveying step.

30 21. A method according to any one of claims 18 to 20, wherein said supplying step comprises supplying said additives in pelletised form.

22. A method according to any one of claims 18 to 21, further comprising, after said supplying step and before said conveying step, blending said additives by a method according to claim 8 or claim 9.

5

23. An apparatus for preparing a blend of additives for incorporation in an asphalt, substantially as hereinbefore described with reference to Figures 2 to 7D.

10 24. A method of blending additives for incorporation in an asphalt, substantially as hereinbefore described with reference to Figures 2 to 7D.

15 25. An apparatus for delivering additives for incorporation in an asphalt to an asphalt mixing box, substantially as hereinbefore described with reference to Figures 2 to 7D.

20 26. A method of delivering additives for incorporation in an asphalt to an asphalt mixing box, substantially as hereinbefore described with reference to Figures 2 to 7D.

ABSTRACT

5 An apparatus and method for blending and for delivering
additives, particularly in pelletised form, into thin
surface dressings for the pavement construction industry,
that provides improved performance compared to existing
methods of manufacture, based on more consistent
10 weighing, blending and transfer of the blended pelletised
additives into an aggregate and bitumen mix. The system
combines ease of handling with cost-effective usage of
pelletised additives and produces consistently higher
quality pavement than can be manufactured today.
